# AirBnB clone - RESTful API

↑ Amateur

👤 By: Guillaume, CTO at Holberton School

⚙️ Weight: 2

🔗 Migrated to checker v2: ✓

✓ Manual review behavior: Any student ⓘ

👥 Project to be done in teams of 2 people

## ➤ Admin corner

🎓 Cohort adjustments

📄 Preview manual QA review sheet (/corrections/preview\_correct?project\_id=2131)

## Concepts

*For this project, we expect you to look at these concepts:*

- AirBnB clone (/concepts/865)
- REST API (/concepts/866)

## Resources

**Read or watch:**

- **REST API** concept page
- Learn REST: A RESTful Tutorial (/rltoken/fMhTwyQ49kBXIRwtZcTj\_A)
- Designing a RESTful API with Python and Flask (/rltoken/Oxdf1xKxpXFDpSnp4PCdCw)
- HTTP access control (CORS) (/rltoken/OKp03yl3mti4AcER1IbAVg)

- Flask cheatsheet (/rltoken/9CMkywW574ITxDsnEJcoVQ)
- (/). • What are Flask Blueprints, exactly? (/rltoken/dic1o0XVvhhZCfJXNWcwhQ)
- Flask (/rltoken/bS5uDfBVJFUESzj-F7Aq3A)
- Modular Applications with Blueprints (/rltoken/7utDLJwGL8gmzG3S2bs4Ag)
- Flask tests (/rltoken/Lu4eNCJxtLgmYHKHLq0ALg)
- Flask-CORS (/rltoken/CHZYO1DIKPi5ZxcPy3dgiA)
- AirBnB clone - RESTful API (/rltoken/HxC-AJeiTbj9H9Bi2vPQVQ)

## Learning Objectives

At the end of this project, you are expected to be able to explain to anyone (/rltoken/vLhVARZfglisDgl2CcYBpw), **without the help of Google**:

### General

- What REST means
- What API means
- What CORS means
- What is an API
- What is a REST API
- What are other type of APIs
- Which is the HTTP method to retrieve resource(s)
- Which is the HTTP method to create a resource
- Which is the HTTP method to update resource
- Which is the HTTP method to delete resource
- How to request REST API

## Requirements

### Python Scripts

- Allowed editors: `vi`, `vim`, `emacs`
- All your files will be interpreted/compiled on Ubuntu 20.04 LTS using python3 (version 3.8.5)
- All your files should end with a new line
- The first line of all your files should be exactly `#!/usr/bin/python3`
- A `README.md` file, at the root of the folder of the project, is mandatory
- Your code should use the `pycodestyle` (version 2.7.\*)
- All your files must be executable
- The length of your files will be tested using `wc`
- All your modules should have documentation ( `python3 -c 'print(__import__("my_module").__doc__)'` )
- All your classes should have documentation ( `python3 -c 'print(__import__("my_module").MyClass.__doc__)'` )
- All your functions (inside and outside a class) should have documentation ( `python3 -c 'print(__import__("my_module").my_function.__doc__)'` and `python3 -c 'print(__import__("my_module").MyClass.my_function.__doc__)'` )
- A documentation is not a simple word, it's a real sentence explaining what's the purpose of the module, class or method (the length of it will be verified)

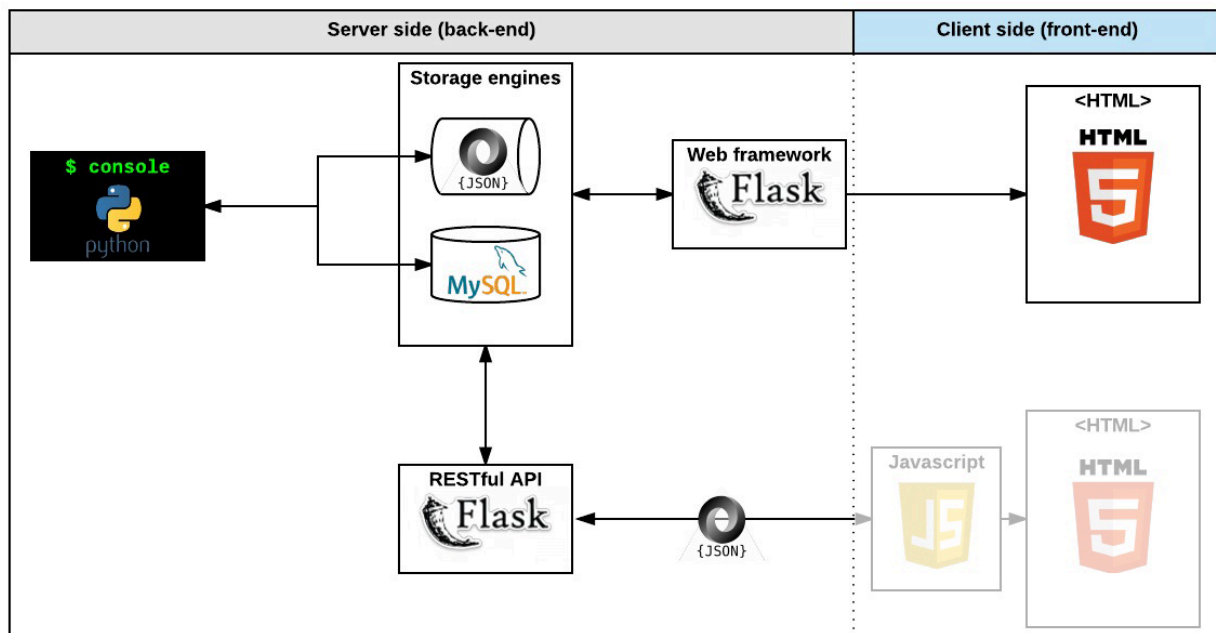

# Python Unit Tests

- Allowed editors: `vi`, `vim`, `emacs`
- All your files should end with a new line
- All your test files should be inside a folder `tests`
- You have to use the `unittest` module (/rltoken/LTMtjq0RnyYyDrSNB28sMQ)
- All your test files should be python files (extension: `.py`)
- All your test files and folders should start by `test_`
- Your file organization in the tests folder should be the same as your project: ex: for `models/base_model.py`, unit tests must be in: `tests/test_models/test_base_model.py`
- All your tests should be executed by using this command: `python3 -m unittest discover tests`
- You can also test file by file by using this command: `python3 -m unittest tests/test_models/test_base_model.py`
- We strongly encourage you to work together on test cases, so that you don't miss any edge cases

## GitHub

There should be one project repository per group. If you clone/fork/whatever a project repository with the same name before the second deadline, you risk a 0% score.

## More Info

## (/) REST API

## Install Flask

```
$ pip3 install Flask
```

# Tasks

### 0. Restart from scratch!

Level: 0

Auto review

No no no! We are already too far in the project to restart everything.

But once again, let's work on a new codebase.

For this project you will fork this codebase ([https://github.com/alexaorrico/AirBnB\\_clone\\_v2.git](https://github.com/alexaorrico/AirBnB_clone_v2.git)):

- Update the repository name to `holbertonschool-AirBnB_clone_v3`
- Update the `README.md` :
  - Add yourself as an author of the project
  - Add new information about your new contribution
  - Make it better!
- If you're the owner of this codebase, create a new repository called `holbertonschool-AirBnB_clone_v3` and copy over all files from `holbertonschool-AirBnB_clone_v2`

#### Repo:

- GitHub repository: `holbertonschool-AirBnB_clone_v3`
- Code language: `python` (project based)

**2 online checks** totalling 10 points about *Python programming*

**1. Never fail!**

Level: 0

Auto review

Since the beginning we've been using the `unittest` module, but do you know why `unittests` are so important? Because when you add a new feature, you refactor a piece of code, etc... you want to be sure you didn't break anything.

At Holberton, we have a lot of tests, and they all pass! Just for the Intranet itself, there are:

- 5,213 assertions (*as of 08/20/2018*)
- 13,061 assertions (*as of 01/25/2021*)

The following requirements **must** be met for your project:

- all current tests must pass (don't delete them...)
- add new tests as much as you can (tests are mandatory for some tasks)

```
guillaume@ubuntu:~/AirBnB_v3$ python3 -m unittest discover tests 2>&1 | tail -1
OK
guillaume@ubuntu:~/AirBnB_v3$ HBNB_ENV=test HBNB_MYSQL_USER=hbnb_test HBNB_MYSQL_PWD
=hbnb_test_pwd HBNB_MYSQL_HOST=localhost HBNB_MYSQL_DB=hbnb_test_db HBNB_TYPE_STORAG
E=db python3 -m unittest discover tests 2>&1 /dev/null | tail -n 1
OK
guillaume@ubuntu:~/AirBnB_v3$
```

**Repo:**

- GitHub repository: holbertonschool-AirBnB\_clone\_v3
- Code language: python (project based)

**2. Code review**

Level: 0

Manual review

Like "tests", code review is the base of all software development.

All companies are using this "feature" to improve the codebase, but also the group dynamic. For example, at Zenly (/rltoken/QSFjhn49V-PPpW1at1bTGg), the iOS team does a code review everyday at 5pm with the entire team.

**What is a code review?**

Code review helps developers learn the code base, as well as help them learn new technologies and techniques that grow their skill sets.

When a developer is finished working on an issue, another developer looks over the code and considers questions like:

- Are there any obvious logic errors in the code?
- Looking at the requirements, are all cases fully implemented?
- Are the new automated tests sufficient for the new code? Do existing automated tests need to be rewritten to account for changes in the code?
- Does the new code conform to existing style guidelines?

As references:

- Why code reviews matter (and actually save time!) (/rltoken/I5Kd0UCfzppHYOheO9np6w)
- Code Review Best Practices (/rltoken/wqqkCUJ-JzN2zZLSap5A\_w)
- GitHub - code review tool (/rltoken/zDP0LJmDM5OBMm\_3P9EtrQ)
- Code Review on GitHub (/rltoken/E3hTBfVz9SfwC3EwqiTTLA)
- Effective pull requests and other good practices for teams using GitHub (/rltoken/WGoARsciXtblI9KpVEFWQw)
- Merging vs. Rebasing (/rltoken/MGSOwpo0fOPYEPNeKLUsA)

For this project, you will need to review a peer's pull request on the branch `storage_get_count` (which will be made for question 3), and then accept the pull request, with your review in the comments.

What we expect:

- a file `code_review.txt`, containing the GitHub username of the student you reviewed (ex: If you did the review of JohnDoe, `code_review.txt` must contain JohnDoe)

- The code review must be done on GitHub, in the comments for the pull request:  
(/)
  - the pull request must be created from the branch `storage_get_count` by a peer
  - only the reviewer can approve the pull request
  - don't delete the branch `storage_get_count` after approval
- The comments must contain at *least* one useful comment:
  - questions about the piece of code, if it's difficult to understand
  - style issues
  - error handling
  - duplicate code
  - potential bugs
  - potential efficiency issues
  - typographical errors

We are all human, we all make mistakes, typos, etc... another developer will always find something in your code.

### Examples of bad reviews

## Storage get count #1

 **Merged** [redacted] merged 2 commits into `master` from `storage_get_count` 4 days ago

 Conversation 9

 Commits 2

 Files changed 4

[redacted] commented 4 days ago

Collaborator

hi

### Examples of good reviews

(/)

[redacted] reviewed on Apr 24, 2017

[View changes](#)

Glad to not see an excess of try/except clauses in the code... variable names are mostly good except for the i, j, k in db\_storage that gets a little unreadable. The efficiency seems to be about as good as you can make it and I appreciate the code comments

[redacted] approved these changes on Apr 24, 2017

[View changes](#)

prototype of get for db/file\_storage is different from assignment: 'id' vs 'id\_'. Probably intentional? Perhaps add more tests for each class when testing get and count?

tests/test\_models/test\_engine/test\_file\_storage.py

```
175 + """
176 +     tests count for all states
177 +     """
178 +     obs_states = models.storage.all('State')
```

[redacted] 4 days ago

same here (what is obs?)

tests/test\_models/test\_engine/test\_db\_storage.py

```
113 +
114 +     def test_get_user2(self):
115 +         test_user = storage.get('User', self.user2.id)
116 +         check =self.user2.id
```

[redacted] 4 days ago

missing space here `check = self.user2.id`**Repo:**

### 3. Improve storage

[Level: 0](#)[Auto review](#)

Update DBStorage and FileStorage , adding two new methods. **All changes should be done in the branch `storage_get_count` :**

A method to retrieve one object:

- Prototype: `def get(self, cls, id):`
  - `cls` : class
  - `id` : string representing the object ID
- Returns the object based on the class and its ID, or `None` if not found

A method to count the number of objects in storage:

- Prototype: `def count(self, cls=None):`
  - `cls` : class (optional)
- Returns the number of objects in storage matching the given class. If no class is passed, returns the count of all objects in storage.

Don't forget to add new tests for these 2 methods on each storage engine.

```

guillaume@ubuntu:~/AirBnB_v3$ cat test_get_count.py
#!/usr/bin/python3

""" Test .get() and .count() methods
"""

from models import storage
from models.state import State

print("All objects: {}".format(storage.count()))
print("State objects: {}".format(storage.count(State)))

first_state_id = list(storage.all(State).values())[0].id
print("First state: {}".format(storage.get(State, first_state_id)))

guillaume@ubuntu:~/AirBnB_v3$
guillaume@ubuntu:~/AirBnB_v3$ HBNB_MYSQL_USER=hbnb_dev HBNB_MYSQL_PWD=hbnb_dev_pwd H
BNB_MYSQL_HOST=localhost HBNB_MYSQL_DB=hbnb_dev_db HBNB_TYPE_STORAGE=db ./test_get_c
ount.py
All objects: 1013
State objects: 27
First state: [State] (f8d21261-3e79-4f5c-829a-99d7452cd73c) {'name': 'Colorado', 'up

## 4. Status of your API

Level: 0

[Auto review](#)

It's time to start your API!

Your first endpoint (route) will be to return the status of your API:

```
guillaume@ubuntu:~/AirBnB_v3$ HBNB_MYSQL_USER=hbnb_dev HBNB_MYSQL_PWD=hbnb_dev_pwd H
BNB_MYSQL_HOST=localhost HBNB_MYSQL_DB=hbnb_dev_db HBNB_TYPE_STORAGE=db HBNB_API_HOS
T=0.0.0.0 HBNB_API_PORT=5000 python3 -m api.v1.app
* Running on http://0.0.0.0:5000/ (Press CTRL+C to quit)
...
```

In another terminal:

```
guillaume@ubuntu:~/AirBnB_v3$ curl -X GET http://0.0.0.0:5000/api/v1/status
{
  "status": "OK"
}
guillaume@ubuntu:~/AirBnB_v3$
guillaume@ubuntu:~/AirBnB_v3$ curl -X GET -s http://0.0.0.0:5000/api/v1/status -vvv
2>&1 | grep Content-Type
< Content-Type: application/json
guillaume@ubuntu:~/AirBnB_v3$
```

Magic right? (No need to have a pretty rendered output, it's a JSON, only the structure is important)

Ok, let starts:

- Create a folder `api` at the root of the project with an empty file `__init__.py`
- Create a folder `v1` inside `api`:
  - create an empty file `__init__.py`
  - create a file `app.py`:
    - create a variable `app`, instance of `Flask`
    - import `storage` from `models`
    - import `app_views` from `api.v1.views`
    - register the blueprint `app_views` to your Flask instance `app`
    - declare a method to handle `@app.teardown_appcontext` that calls `storage.close()`
    - inside `if __name__ == "__main__":`, run your Flask server (variable `app`) with:
      - `host` = environment variable `HBNB_API_HOST` or `0.0.0.0` if not defined
      - `port` = environment variable `HBNB_API_PORT` or `5000` if not defined
      - `threaded=True`
- Create a folder `views` inside `v1`:
  - create a file `__init__.py`:
    - import `Blueprint` from `flask` doc (/rltoken/7utDLJwGL8gmzG3S2bs4Ag)
    - create a variable `app_views` which is an instance of `Blueprint` (url prefix must be `/api/v1`)

( / )

- below the above line for `app_views` , add a wildcard import of everything in the package `api.v1.views.index` => PEP8 will complain about it, don't worry, it's normal and this file ( `v1/views/__init__.py` ) won't be check. Placing the import declaration here will avoid circular import errors later.
- create a file `index.py`
  - import `app_views` from `api.v1.views`
  - create a route `/status` on the object `app_views` that returns a JSON: `"status": "OK"` (see example)

**Repo:**

- GitHub repository: `holbertonschool-AirBnB_clone_v3`
- File: `api/__init__.py`, `api/v1/__init__.py`, `api/v1/views/__init__.py`, `api/v1/views/index.py`, `api/v1/app.py`
- Code language: python (project based)

**5. Some stats?**

Level: 0

Auto review

Create an endpoint that retrieves the number of each objects by type:

- In `api/v1/views/index.py`
- Route: `/api/v1/stats`
- You must use the newly added `count()` method from `storage`

```
guillaume@ubuntu:~/AirBnB_v3$ curl -X GET http://0.0.0.0:5000/api/v1/stats
{
  "amenities": 47,
  "cities": 36,
  "places": 154,
  "reviews": 718,
  "states": 27,
  "users": 31
}
guillaume@ubuntu:~/AirBnB_v3$
```

*(No need to have a pretty rendered output, it's a JSON, only the structure is important)***Repo:**

- GitHub repository: `holbertonschool-AirBnB_clone_v3`
- File: `api/v1/views/index.py`
- Code language: python (project based)

**9 online checks** totalling 11 points about *Python programming*[Show \(/tasks/19573\)](/tasks/19573)[Edit \(/tasks/19573/edit\)](/tasks/19573/edit)[Test correction](#)[Done by](#)[Copy to another project](#)[Export checks to JSON](#)[Import checks from JSON](#)[>\\_ Get a sandbox](#)**6. Not found****Level: 0****Auto review**

Designers are really creative when they have to design a "404 page", a "Not found"... 34 brilliantly designed 404 error pages (</rltoken/8y7GgrPmjVcq-vZoeQ60yQ>)

Today it's different, because you won't use HTML and CSS, but JSON!

In `api/v1/app.py`, create a handler for 404 errors that returns a JSON-formatted 404 status code response. The content should be: `"error": "Not found"`

```
guillaume@ubuntu:~/AirBnB_v3$ curl -X GET http://0.0.0.0:5000/api/v1/nop
{
  "error": "Not found"
}
guillaume@ubuntu:~/AirBnB_v3$ curl -X GET http://0.0.0.0:5000/api/v1/nop -vvv
* Trying 0.0.0.0...
* TCP_NODELAY set
* Connected to 0.0.0.0 (127.0.0.1) port 5000 (#0)
> GET /api/v1/nop HTTP/1.1
> Host: 0.0.0.0:5000
> User-Agent: curl/7.51.0
> Accept: */*
>
* HTTP 1.0, assume close after body
< HTTP/1.0 404 NOT FOUND
< Content-Type: application/json

## 7. State

Level: 0

Auto review

Create a new view for `State` objects that handles all default RESTful API actions:

- In the file `api/v1/views/states.py`
- You must use `to_dict()` to retrieve an object into a valid JSON
- Update `api/v1/views/__init__.py` to import this new file

Retrieves the list of all `State` objects: `GET /api/v1/states`

Retrieves a `State` object: `GET /api/v1/states/<state_id>`

- If the `state_id` is not linked to any `State` object, raise a `404` error

Deletes a `State` object: `DELETE /api/v1/states/<state_id>`

- If the `state_id` is not linked to any `State` object, raise a `404` error
- Returns an empty dictionary with the status code `200`

Creates a `State`: `POST /api/v1/states`

- You must use `request.get_json` from Flask to transform the HTTP body request to a dictionary
- If the HTTP body request is not valid JSON, raise a `400` error with the message `Not a JSON`
- If the dictionary doesn't contain the key `name`, raise a `400` error with the message `Missing name`
- Returns the new `State` with the status code `201`

Updates a `State` object: `PUT /api/v1/states/<state_id>`

- If the `state_id` is not linked to any `State` object, raise a `404` error
- You must use `request.get_json` from Flask to transform the HTTP body request to a dictionary
- If the HTTP body request is not valid JSON, raise a `400` error with the message `Not a JSON`
- Update the `State` object with all key-value pairs of the dictionary.
- Ignore keys: `id`, `created_at` and `updated_at`
- Returns the `State` object with the status code `200`

```
guillaume@ubuntu:~/AirBnB_v3$ curl -X GET http://0.0.0.0:5000/api/v1/states/
{
  {
    "__class__": "State",
    "created_at": "2017-04-14T00:00:02",

## 8/City

Level: 0

Auto review

Same as `State`, create a new view for `City` objects that handles all default RESTful API actions:

- In the file `api/v1/views/cities.py`
- You must use `to_dict()` to serialize an object into valid JSON
- Update `api/v1/views/__init__.py` to import this new file

Retrieves the list of all `City` objects of a `State`: `GET /api/v1/states/<state_id>/cities`

- If the `state_id` is not linked to any `State` object, raise a `404` error

Retrieves a `City` object.: `GET /api/v1/cities/<city_id>`

- If the `city_id` is not linked to any `City` object, raise a `404` error

Deletes a `City` object: `DELETE /api/v1/cities/<city_id>`

- If the `city_id` is not linked to any `City` object, raise a `404` error
- Returns an empty dictionary with the status code `200`

Creates a `City`: `POST /api/v1/states/<state_id>/cities`

- You must use `request.get_json` from Flask to transform the HTTP body request to a dictionary
- If the `state_id` is not linked to any `State` object, raise a `404` error
- If the HTTP body request is not a valid JSON, raise a `400` error with the message `Not a JSON`
- If the dictionary doesn't contain the key `name`, raise a `400` error with the message `Missing name`
- Returns the new `City` with the status code `201`

Updates a `City` object: `PUT /api/v1/cities/<city_id>`

- If the `city_id` is not linked to any `City` object, raise a `404` error
- You must use `request.get_json` from Flask to transform the HTTP body request to a dictionary
- If the HTTP request body is not valid JSON, raise a `400` error with the message `Not a JSON`
- Update the `City` object with all key-value pairs of the dictionary
- Ignore keys: `id`, `state_id`, `created_at` and `updated_at`
- Returns the `City` object with the status code `200`

```
guillaume@ubuntu:~/AirBnB_v3$ curl -X GET http://0.0.0.0:5000/api/v1/states/not_an_id/cities/

## 9. Amenity

Level: 0

Auto review

Create a new view for `Amenity` objects that handles all default RESTful API actions:

- In the file `api/v1/views/amenities.py`
- You must use `to_dict()` to serialize an object into valid JSON
- Update `api/v1/views/__init__.py` to import this new file

Retrieves the list of all `Amenity` objects: GET `/api/v1/amenities`

Retrieves a `Amenity` object: GET `/api/v1/amenities/<amenity_id>`

- If the `amenity_id` is not linked to any `Amenity` object, raise a 404 error

Deletes a `Amenity` object: DELETE `/api/v1/amenities/<amenity_id>`

- If the `amenity_id` is not linked to any `Amenity` object, raise a 404 error
- Returns an empty dictionary with the status code 200

Creates a `Amenity`: POST `/api/v1/amenities`

- You must use `request.get_json` from Flask to transform the HTTP request to a dictionary
- If the HTTP request body is not valid JSON, raise a 400 error with the message `Not a JSON`
- If the dictionary doesn't contain the key `name`, raise a 400 error with the message `Missing name`
- Returns the new `Amenity` with the status code 201

Updates a `Amenity` object: PUT `/api/v1/amenities/<amenity_id>`

- If the `amenity_id` is not linked to any `Amenity` object, raise a 404 error
- You must use `request.get_json` from Flask to transform the HTTP request to a dictionary
- If the HTTP request body is not valid JSON, raise a 400 error with the message `Not a JSON`
- Update the `Amenity` object with all key-value pairs of the dictionary

- Ignore keys: `id`, `created_at` and `updated_at`
- (/). Returns the `Amenity` object with the status code `200`

**Repo:**

- GitHub repository: `holbertonschool-AirBnB_clone_v3`

**10. User**
**Level: 0**
[Auto review](#)

Create a new view for `User` object that handles all default RESTful API actions:

- In the file `api/v1/views/users.py`
- You must use `to_dict()` to retrieve an object into a valid JSON
- Update `api/v1/views/__init__.py` to import this new file

Retrieves the list of all `User` objects: `GET /api/v1/users`

Retrieves a `User` object: `GET /api/v1/users/<user_id>`

- If the `user_id` is not linked to any `User` object, raise a `404` error

Deletes a `User` object:: `DELETE /api/v1/users/<user_id>`

- If the `user_id` is not linked to any `User` object, raise a `404` error
- Returns an empty dictionary with the status code `200`

Creates a `User`: `POST /api/v1/users`

- You must use `request.get_json` from Flask to transform the HTTP body request to a dictionary
- If the HTTP body request is not valid JSON, raise a `400` error with the message `Not a JSON`
- If the dictionary doesn't contain the key `email`, raise a `400` error with the message `Missing email`
- If the dictionary doesn't contain the key `password`, raise a `400` error with the message `Missing password`
- Returns the new `User` with the status code `201`

Updates a `User` object: `PUT /api/v1/users/<user_id>`

- If the `user_id` is not linked to any `User` object, raise a `404` error
- You must use `request.get_json` from Flask to transform the HTTP body request to a dictionary
- If the HTTP body request is not valid JSON, raise a `400` error with the message `Not a JSON`
- Update the `User` object with all key-value pairs of the dictionary
- Ignore keys: `id`, `email`, `created_at` and `updated_at`
- Returns the `User` object with the status code `200`

**Repo:**

## 13. HTTP access control (CORS)

**Level: 0****Auto review**

A resource makes a cross-origin HTTP request when it requests a resource from a different domain, or port, than the one the first resource itself serves.

Read the full definition here (`/rltoken/OKp03yl3mti4AcER1IbAVg`)

Why do we need this?

Because you will soon start allowing a web client to make requests your API. If your API doesn't have a correct CORS setup, your web client won't be able to access your data.

With Flask, it's really easy, you will use the class `CORS` of the module `flask_cors`.

How to install it: `$ pip3 install flask_cors`

Update `api/v1/app.py` to create a `CORS` instance allowing: `/*` for `0.0.0.0`

You will update it later when you will deploy your API to production.

Now you can see this HTTP Response Header: `< Access-Control-Allow-Origin: 0.0.0.0`

```
guillaume@ubuntu:~/AirBnB_v3$ curl -X GET http://0.0.0.0:5000/api/v1/cities/1da255c0-f023-4779-8134-2b1b40f87683 -vvv

Create a new view for the link between `Place` objects and `Amenity` objects that handles all default RESTful API actions:

- In the file `api/v1/views/places_amenities.py`
- You must use `to_dict()` to retrieve an object into a valid JSON
- Update `api/v1/views/__init__.py` to import this new file
- Depending of the storage:
  - `DBStorage`: list, create and delete `Amenity` objects from `amenities` relationship
  - `FileStorage`: list, add and remove `Amenity` ID in the list `amenity_ids` of a `Place` object

Retrieves the list of all `Amenity` objects of a `Place`: `GET /api/v1/places/<place_id>/amenities`

- If the `place_id` is not linked to any `Place` object, raise a `404` error

Deletes a `Amenity` object to a `Place`: `DELETE /api/v1/places/<place_id>/amenities/<amenity_id>`

- If the `place_id` is not linked to any `Place` object, raise a `404` error
- If the `amenity_id` is not linked to any `Amenity` object, raise a `404` error
- If the `Amenity` is not linked to the `Place` before the request, raise a `404` error
- Returns an empty dictionary with the status code `200`

Link a `Amenity` object to a `Place`: `POST /api/v1/places/<place_id>/amenities/<amenity_id>`

- No HTTP body needed
- If the `place_id` is not linked to any `Place` object, raise a `404` error
- If the `amenity_id` is not linked to any `Amenity` object, raise a `404` error
- If the `Amenity` is already linked to the `Place`, return the `Amenity` with the status code `200`
- Returns the `Amenity` with the status code `201`

## 15. Security improvements!

**Level: 1****Auto review**

Currently, the `User` object is designed to store the user password in cleartext.

It's super bad!

To avoid that, improve the `User` object:

- Update the method `to_dict()` of `BaseModel` to remove the `password` key **except when it's used by `FileStorage` to save data to disk**. Tips: default parameters
- Each time a new `User` object is created or password updated, the password is hashed to a MD5 (`rltoken/Brsva-5VAnrPZFTwKDx32A`) value
- In the database for `DBStorage`, the password stored is now hashed to a MD5 value
- In the file for `FileStorage`, the password stored is now hashed to a MD5 value

## 16. Search

**Level: 1****Auto review**

For the moment, the only way to list `Place` objects is via `GET /api/v1/cities/<city_id>/places`.

Good, but not enough...

Update `api/v1/views/places.py` to add a new endpoint: `POST /api/v1/places_search` that retrieves all `Place` objects depending of the JSON in the body of the request.

The JSON can contain 3 optional keys:

- `states`: list of `State` ids
- `cities`: list of `City` ids
- `amenities`: list of `Amenity` ids

Search rules:

- If the HTTP request body is not valid JSON, raise a `400` error with the message `Not a JSON`

- If the JSON body is empty or each list of all keys are empty: retrieve all `Place` objects
- (/). • If `states` list is not empty, results should include all `Place` objects for each `State` id listed
- If `cities` list is not empty, results should include all `Place` objects for each `City` id listed
- Keys `states` and `cities` are inclusive. Search results should include all `Place` objects in storage related to each `City` in every `State` listed in `states`, plus every `City` listed individually in `cities`, *unless* that `City` was already included by `states`.
  - Context:
    - State A has 2 cities A1 and A2
    - State B has 3 cities B1, B2 and B3
    - A1 has 1 place
    - A2 has 2 places
    - B1 has 3 places
    - B2 has 4 places
    - B3 has 5 places
  - Search: `states` = State A and `cities` = B2
  - Result: all 4 places from the city B2 and the place from the city A1 and the 2 places of the city A2 (because they are part of State A) => 7 places returned
- If `amenities` list is not empty, limit search results to only `Place` objects having all `Amenity` ids listed
- The key `amenities` is exclusive, acting as a filter on the results generated by `states` and `cities`, or on all `Place` if `states` and `cities` are both empty or missing.
- Results will only include `Place` objects having all listed `amenities`. If a `Place` doesn't have even one of these `amenities`, it won't be retrieved.

## 17. Documentation

**Level: 1****Manual review**

Nothing better than writing tests... and documentation!

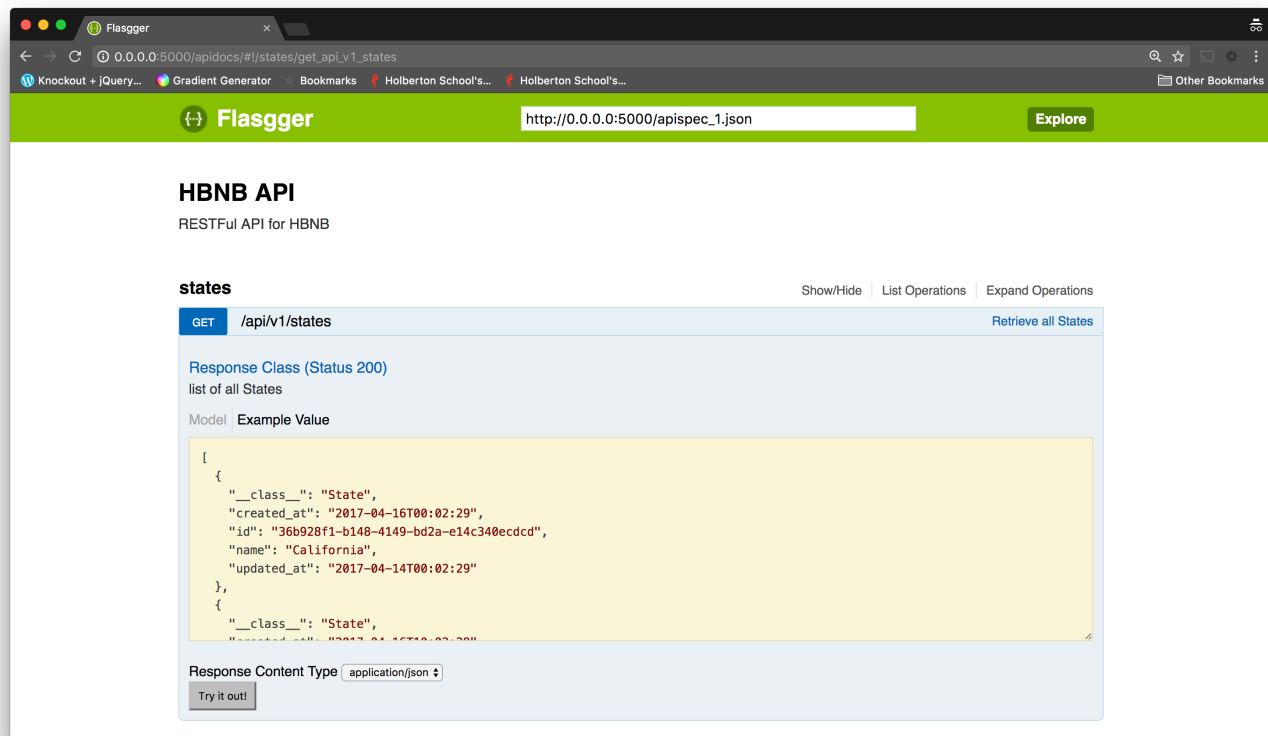

But with Swagger (/rltoken/TitPF0B8BQO9QijVVr6Cmg), it's really easy!

You will use the Flask version of Swagger: Flasgger (/rltoken/2D0XUVa\_ra-K7Y-ZW87CSg)

How to install it: `$ pip3 install flasgger`

Add comments on each endpoint of your API, so you can view the documentation in your browser:

`http://0.0.0.0:5000/apidocs`

**It is your responsibility to request a review for this task from a peer before the project's deadline. If no peers have been reviewed, you should request a review from a TA or staff member.**
